

A minimal model for self-assembling hollow shells and 2D quasicrystals from colloidal building blocks

Szilard Fejer

Provitam Foundation

How do we define shape on the mesoscopic length scale?

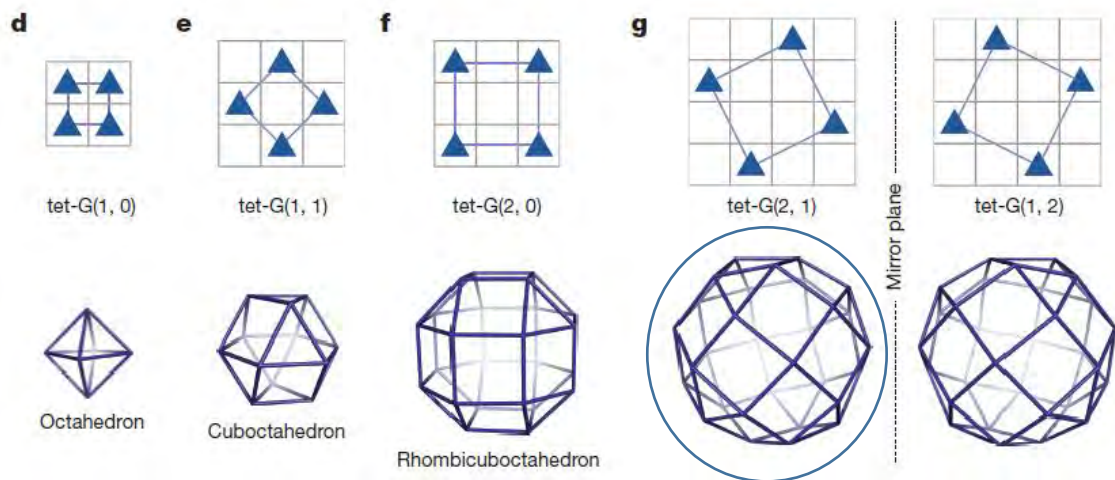

- Interactions and shape “go together like a horse and carriage ... You can’t have one, you can’t have none, you can’t have one without the other” (Sinatra)
- We are interested in what can we encode in terms of emergent behaviour in simple building blocks

Dall-E (prompt: a sad triangular particle figure looking at an interaction between two spherical particles)

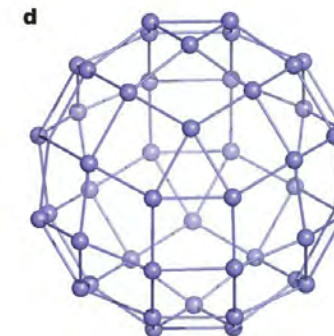

Molecular Goldberg cages

Fujita et al., Nature 540, 563-566 (2016)

30

48

the largest molecular cage to date

Hollow shells

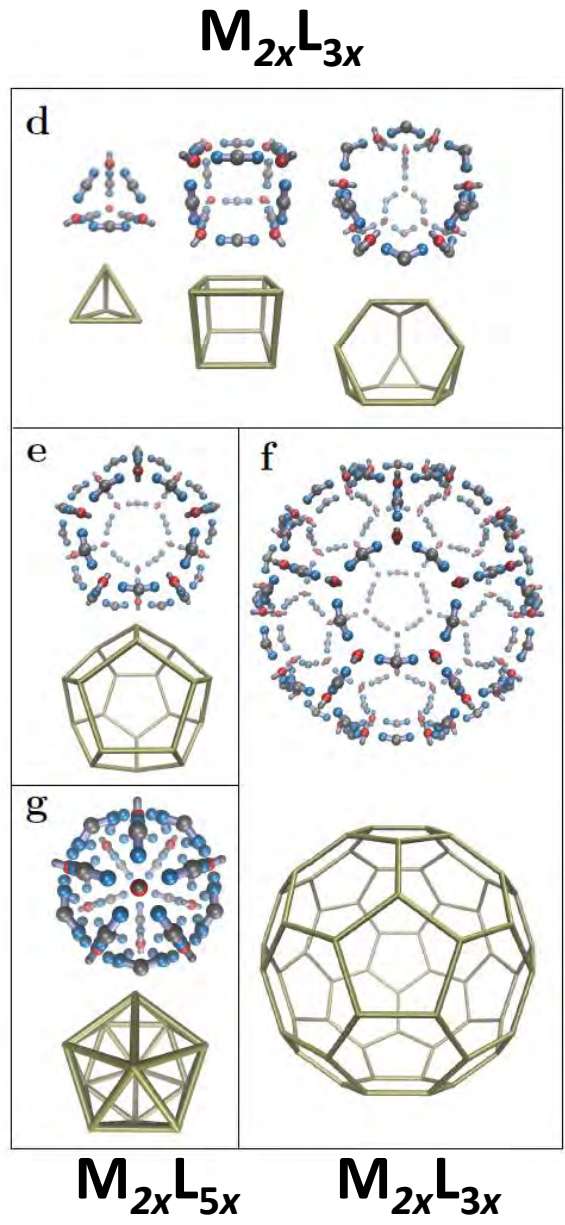

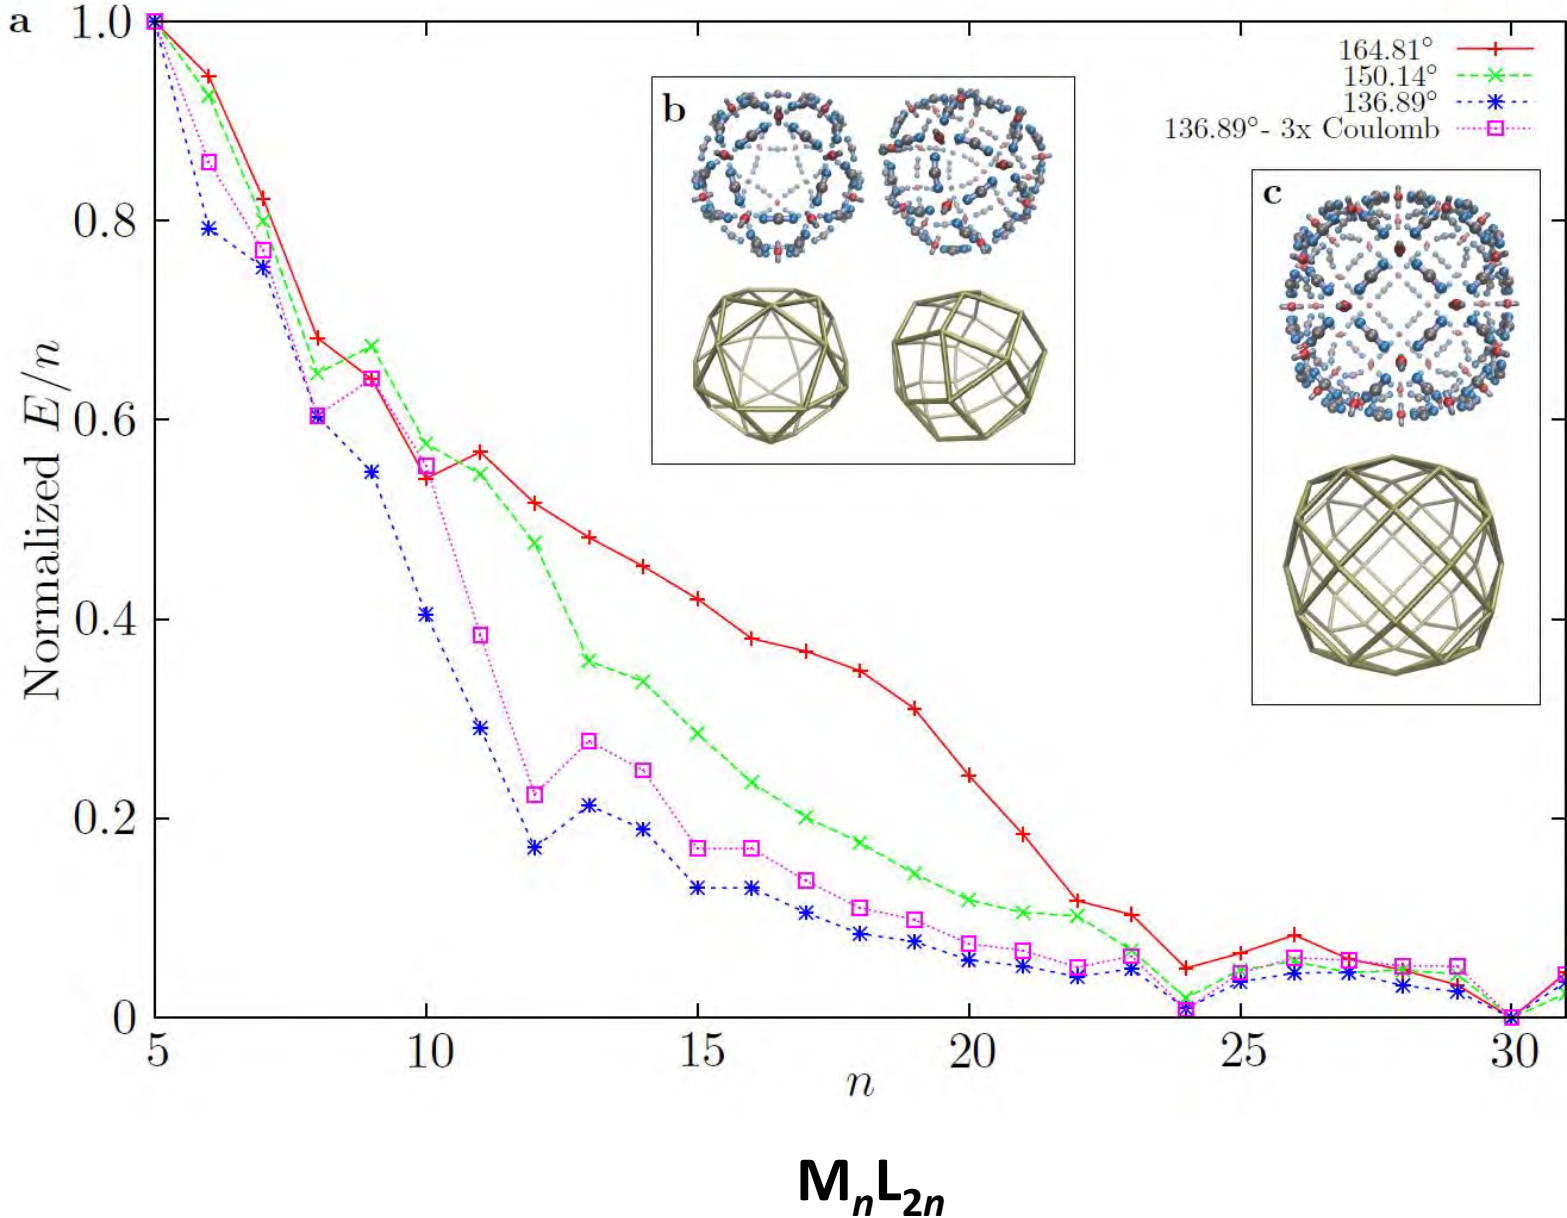

- What are the minimal conditions to replicate self-assembly into hollow shells in a binary system?
- Particle shape depends on the anisotropy of interactions with its neighbours – it is not an absolute value
- Interaction is fairly long range, compared to particle size

$$V = \sum_{i < j} \left(\frac{\epsilon_{ij}^{\text{rep}}}{r_{ij}^{12}} + \epsilon^{\text{Q}} \frac{q_i q_j}{r_{ij}} \right)$$

Global optimization

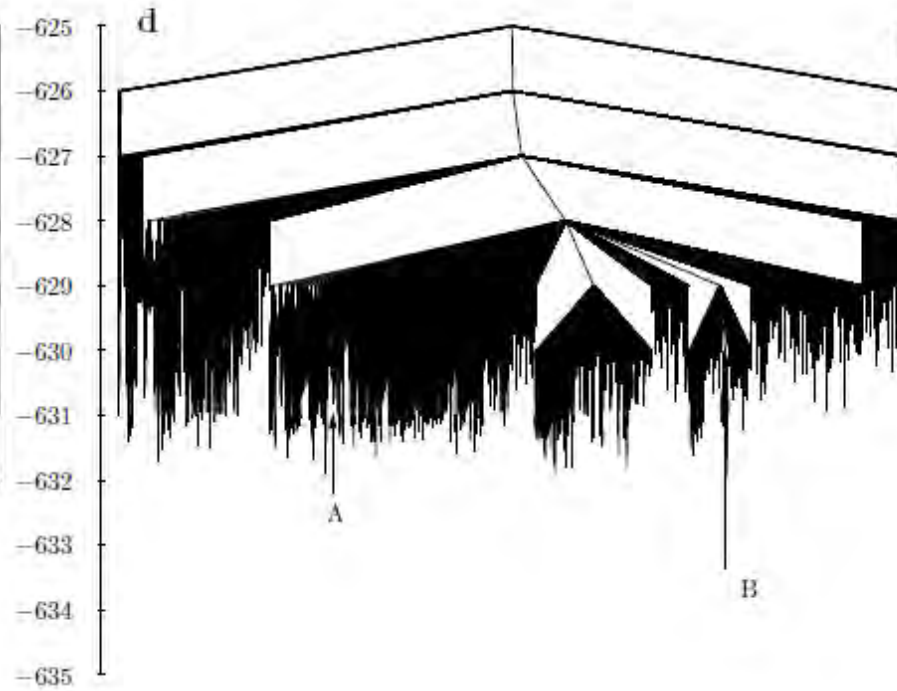

pseudorhombicuboctahedral to
rhombicuboctahedral transition

highly cooperative
single transition state rearrangement

A
chiral tetraivalent Goldberg

B
dodecahedral

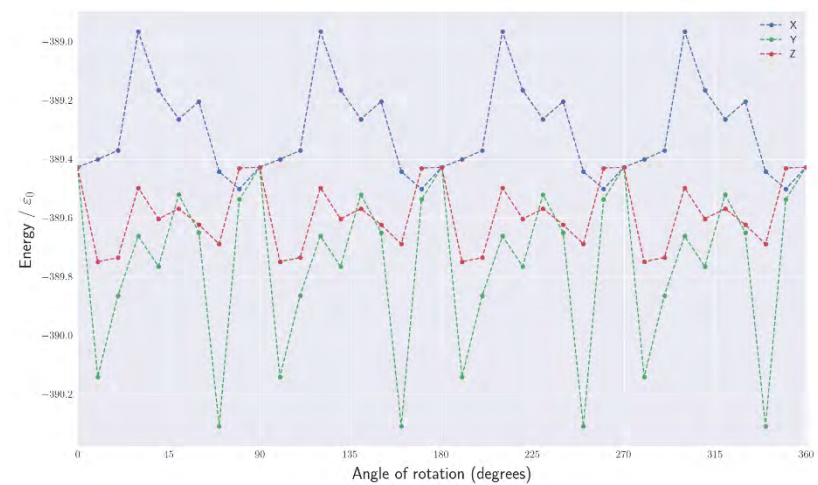

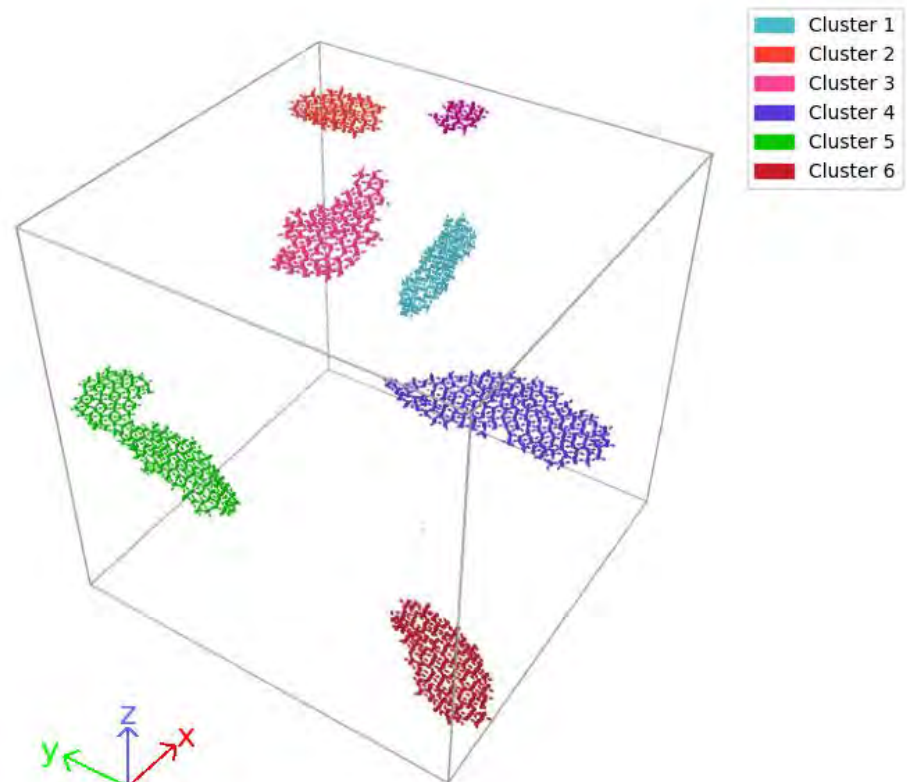

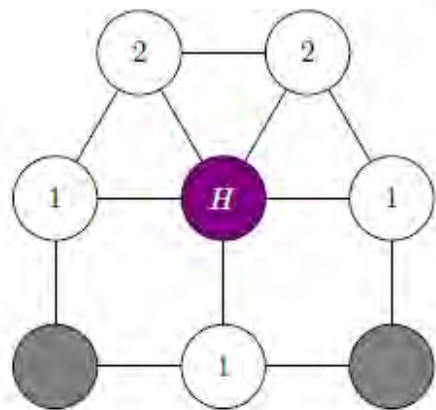

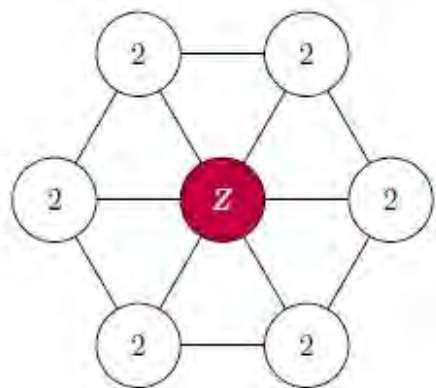

2D quasicrystalline approximants

- linear building blocks
- two competing forces: planar vs fivefold coordination

Two-layered structures: the first layer acts as a template

A; peak width=20
